

Density Dependence

Simulations

L Kell

15 December, 2022

This document provides an example of how to model density dependence in mass-at-age and M-at-age.

The life history parameters of mackerel are used to construct an **FLBRP** object that represents the equilibrium dynamics, this is then used to construct an **FLStock** object that models the time series dynamics.

The Lorenzen relationship between mass-at-age and M is used to link M and weight-at-age. For example, $\text{lorenzen } M = a \cdot 300^{-0.288}$, so if you want $M=0.2$ at 300g then $a = 0.2 / (300^{-0.288})$
